

Setup Instructions for Running the Repository on Your Device

This project runs through Docker, so it will **not** use the default Rails port (`localhost:3000`). Instead, access it through `localhost:8080`.

1. Install Docker Desktop

Download and install Docker Desktop:

<https://docs.docker.com/desktop/>

Once installed, open the app. You do **not** need to create an account.

2. Clone the Repository

Download the project from GitHub to your device using Git:

1. `git clone <repository-url>`
2. `cd <repository-folder>`

Replace `<repository-url>` with the repository link.

3. Create the Environment File

Run the following commands in Terminal:

3. `touch .env.development`
4. `nano .env.development`

This opens a file where you can paste the following:

```
RAILS_ENV=development

POSTGRES_DB=app_development
POSTGRES_USER=postgres
POSTGRES_PASSWORD=postgres
POSTGRES_HOST=db
```

```
POSTGRES_PORT=5432

DATABASE_URL=postgresql://postgres:postgres@db:5432/app_development
SENDGRID_API_KEY=SG.hljZ-NsgRnO9uV4VCj2BKg.unM7_TD-0qm8Mv_B1C
Rp9zMEpRvXaFOA-p3ulpZdDMM
LLM_API_URL=http://[Cloud VM's External IP]:11434
LLM_MODEL=gemma4:e2b
LLM_TIMEOUT_SECONDS=300
```

After pasting:

- Press **Control + O** to save
- Press **Enter** to confirm
- Press **Control + X** to exit

4. Build and Start the Application

Run:

- 5. docker-compose up --build
- 6. rails db:seed (on the docker console by going to web-1 and clicking EXEC) (Screenshots shown)

This may take a few minutes the first time.

5. Open the Application

Once everything finishes loading, open your browser and go to:

`http://localhost:8080`

Notes

- Do **not** use `localhost:3000` for this project.
- Make sure Docker Desktop is running before using `docker compose up`.
- If changes are made later, rerun:
 - `docker compose up`
- 11434 is the port Ollama uses
- When resetting the database, you have to do it on the docker console and not your device terminal. This works the same for seeding the database.
